NEW QUESTION: 1

DNS is a distributed database system that stores information about domain names and their corresponding IP addresses. It is a critical component of the Internet infrastructure. The DNS hierarchy is organized into a tree structure, with the root at the top and domain names branching out below. Each domain name is associated with a specific IP address, which is used to locate and retrieve the content of the domain. The DNS system is responsible for translating domain names into IP addresses, and vice versa. This process is known as DNS resolution. The DNS system is a distributed system, meaning that it is spread across multiple servers and locations. This makes it highly resilient and available. The DNS system is also a hierarchical system, with the root at the top and domain names branching out below.
